Introduction to model evaluation/validation

Stephanie J. Spielman

Data Science for Biologists, Spring 2020

Model evaluation and prediction

- R^2 tells how how much variation is explained in the data the model was FIT ON
 - o fit on <===> "trained on"
- How good is the model at explaining variation in data it does NOT know about?
 - Should we even bother using our model to predict future outcomes?

More measures of model evaluation

- RMSE ("Root mean squared error") and MAE ("Mean absolute error")
 - Easily interpreted in units of "Y"
 - RMSE is very common! "Average" error we can expect when using this model
- Less easily interpreted, but also commonly-used evaluation measurements
 - MSE = mean squared error

modelr makes life easy!!

```
# use trace = F to suppress excessive output which hurts my eyeballs
fit <- step( lm(Sepal.Length ~ ., data = iris), trace = F )</pre>
broom::tidy(fit)
## # A tibble: 6 x 5
                 estimate std.error statistic p.value
## term
                  ## <chr>
## 1 (Intercept)
                 2.17 0.280 7.76 1.43e-12
## 2 Sepal.Width 0.496 0.0861 5.76 4.87e- 8
## 3 Petal.Length 0.829 0.0685 12.1 1.07e-23
## 4 Petal.Width
              -0.315 0.151 -2.08 3.89e- 2
## 5 Speciesversicolor -0.724 0.240 -3.01 3.06e- 3
## 6 Speciesvirginica -1.02 0.334 -3.07 2.58e- 3
broom::glance(fit)
## # A tibble: 1 x 11
## r.squared adj.r.squared sigma statistic p.value df logLik AIC
                                                          BIC
## <dbl>
              0.867
                 0.863 0.307 188. 2.67e-61 6 -32.6 79.1 100.
## # ... with 2 more variables: deviance <dbl>, df.residual <int>
```

```
## Obtain R^2 quickly with modelr
modelr::rsquare(fit, iris)
## [1] 0.8673123

## Obtain RMSE quickly with modelr
modelr::rmse(fit, iris)
## [1] 0.300627
```

Use that model going forward easily

```
## reminding you of the fit variable:
fit <- step( lm(Sepal.Length ~ ., data = iris), trace = F )</pre>
## Extract the FORMULA as fit$formula
lm(fit$formula, data = iris)
##
## Call:
## lm(formula = fit$formula, data = iris)
## Coefficients:
        (Intercept) Sepal.Width
                                            Petal.Length
                               0.4959
                                                  0.8292
             2.1713
##
     Petal.Width Speciesversicolor Speciesvirginica
                              -0.7236
##
            -0.3152
                                                 -1.0235
```

Validation with testing/training

- Randomly **split** your dataset into two parts:
 - The "training" part (usually 60-80% of the data) **builds** aka **trains** the model
 - The "testing" part (the remaining 20-40%) evaluates aka **tests** the performance of the model
 - If model performs terribly on testing data, suggests model was *overfit*
 - Either way, performance is usually better on training data. Why?

Cross validation with a training and testing split

```
# Use dplyr::sample_frac() to randomly sample a fraction of rows
training_iris <- sample_frac(iris, 0.7) ## 70% into training
nrow(training_iris)
## [1] 105</pre>
```

```
# Get the "anti training" for testing.. with anti_join()!
# In anti_join(), the FULL data goes FIRST!!
testing_iris <- anti_join(iris, training_iris) ## remaining 30% into training
## Joining, by = c("Sepal.Length", "Sepal.Width", "Petal.Length",
## "Petal.Width", "Species")
nrow(testing_iris)
## [1] 45</pre>
```

```
## TRAIN the model on training data: data = training_iris !!
trained_model <- lm(fit$formula, data = training_iris)</pre>
```

• We should **NOT** use **step()** here. WHY?????

Compare training metrics to those on TESTING data

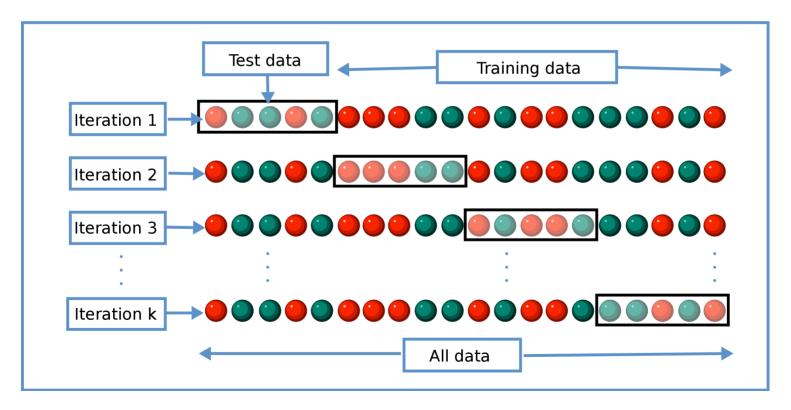

```
## How does the model do on data it was TRAINED ON?
modelr::rsquare(trained_model, training_iris)
## [1] 0.8704271
modelr::rmse(trained_model, training_iris)
## [1] 0.3009213

## How does the model do on data it has NEVER SEEN? The testing data!!
modelr::rsquare(trained_model, testing_iris)
## [1] 0.8502678
modelr::rmse(trained_model, testing_iris)
```

[1] 0.3090084

K-fold cross validation

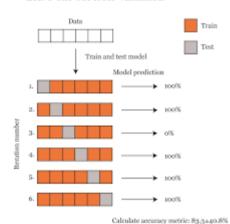

- Randomly divide the whole dataset into "K" equal chunks aka folds
- Perform K iterations of model training and testing
 - "Hold back" data each time for testing!
- ullet Get RMSE and R^2 for each iteration, and look at full distribution

More robust: Leave-one-out cross validation (LOOCV)

- K-folds on speed: each "test" size is N=1!!
- For small datasets, LOOCV probably "better"

Leave-one-out cross-validation

Running a K-fold CV to evaluate a model that predict Sepal Lengths

```
# decide your K!
folds <- 10
# Use the amazzzzing function modelr::crossv_kfold()
crossv_kfold(iris, folds)
## # A tibble: 10 x 3
                                .id
   train
                   test
   <named list> <named list> <chr>
   1 <resample> <resample>
                               0.1
   2 <resample> <resample>
                               02
   3 <resample> <resample>
                               03
   4 <resample>
                 <resample>
##
                               04
   5 <resample>
                 <resample>
                               05
   6 <resample>
                 <resample>
                               06
   7 <resample>
                  <resample>
                               07
   8 <resample>
                  <resample>
                               08
   9 <resample>
                  <resample>
                               09
## 10 <resample>
                  <resample>
                               10
```

A necessary detour: functional programming with **purrr**

```
## log of a number
log(5)
## [1] 1.609438

## log of an array of numbers
log(1:4)
## [1] 0.0000000 0.6931472 1.0986123 1.3862944
```

```
## using purrr::map returns a !!!LIST!!!

purrr::map(1:4, log))

## [[1]]

## [2]]

## [3]]

## [3]]

## [4]]

## [4]]

## [4]]

## [1] 1.386294
```

map_TYPE to specify a different type of output

```
## purrr, I'd really like an array of *doubles* to come out of this
purrr::map_dbl(1:4, log)
## [1] 0.00000000 0.6931472 1.0986123 1.3862944

## map2 means there are TWO inputs
## recall: log has a second optional argument for BASE! The output is log base 2
purrr::map2_dbl(1:4, 2, log)
## [1] 0.0000000 1.0000000 1.584963 2.000000
```

A second necessary detour: writing our own functions

```
add_two_numbers <- function(a, b)
{
   a + b
}

add_two_numbers(10, 12)
## [1] 22
add_two_numbers(5, -5)
## [1] 0</pre>
```

Back to K-fold

```
crossv_kfold(iris, folds) -> iris_kfold
iris_kfold
## # A tibble: 10 x 3
   train
                   test
                                .id
   <named list> <named list> <chr>
   1 <resample> <resample>
                                01
##
   2 <resample>
                  <resample>
                                02
##
   3 <resample>
                   <resample>
                                03
##
   4 <resample>
                   <resample>
                                04
   5 <resample>
                   <resample>
                                05
   6 <resample>
                   <resample>
                                06
   7 <resample>
                   <resample>
##
                                07
##
   8 <resample>
                   <resample>
                                08
   9 <resample>
                   <resample>
                                09
## 10 <resample>
                   <resample>
                                10
```

Using purrr: : map to run a model at each row

```
## DEFINE THE FUNCTION!! IT'S JUST THE MODEL!!!
## THIS IS IMPORTANT: As written ASSUMES (!!!!!!) fir$formula was defined in code
ABOVE this function
my_iris_model <- function(input_data){</pre>
  lm(fit$formula, data = input data)
iris kfold %>%
 mutate( model_fit = purrr::map( train, my_iris_model ) )
## # A tibble: 10 x 4

                                                              0.866
```

Putting it all together: model selection and k-fold CV

Summarizing our results

- We expect, when used on data the model has never seen, it will predict \mathbb{R}^2 of variation in sepal lengths
- We expect, when used on data the model has never seen, the model predictions will be roughly *RMSE* units off (the average residual is the RMSE value)

```
summary(iris$Sepal.Length)
## Min. 1st Qu. Median Mean 3rd Qu. Max.
## 4.300 5.100 5.800 5.843 6.400 7.900
```

Visualizing our evaluation

• Any kind of standard continuous distribution plot will do here:

```
result_kfold %>%
  ggplot(aes(x = "", y = test_rmse)) + geom_boxplot() +
  xlab("") + ylab("Mean RMSE") -> box_rmse

result_kfold %>%
  ggplot(aes(x = "", y = test_rsq)) + geom_boxplot() +
  xlab("") + ylab("Mean R^2") -> box_rsw

# patchwork
print(box_rmse+box_rsw)
```

How to do LOOCV?

- Same exact way except use modelr::crossv_loo()
 - BUT I think there's a bug in **rsquare()** when used on LOO output, so let's just do RMSE.

Making predictions!

Once we have our model, we can predict future outcomes.

```
# reminder for what our model predictors are
broom::tidy(fit)
## # A tibble: 6 x 5
           estimate std.error statistic p.value
##
  term
  <chr>
                      2.17 0.280 7.76 1.43e-12
## 1 (Intercept)

      0.496
      0.0861
      5.76 4.87e-8

      0.829
      0.0685
      12.1 1.07e-23

## 2 Sepal.Width
## 3 Petal.Length
## 4 Petal.Width
                 -0.315 0.151 -2.08 3.89e- 2
## 5 Speciesversicolor -0.724 0.240 -3.01 3.06e- 3
## 6 Speciesvirginica -1.02
                              0.334
                                           -3.07 2.58e- 3
```

Making predictions!

• Predict using a tibble with columns **EXACTLY NAMED** as model predictor variables in the model formula

BONUS Q: Why did the **modelr** authors flip these arguments?
